Synthesis:

One interviewee dealt with Hurricane Sandy, one of the strongest hurricanes to hit the East Coast. My interviewee found out about Hurricane Sandy from the news and just knew the basics, but didn't know how strong it would be, and how much damage it would've caused. They just prayed everything would be ok, and thankfully it was. If only my interviewee knew what could happen best case scenario and worse case scenario, they wouldn't have to worry that much. What surprised me: the lack of advanced knowledge of these storms. The real problem is that the potential damage it could cause not being shared is worrying. These people who are in a hit radius of a storm should know what to do and what to expect in a best and worst case scenario.

Problem Statement:
People get little to no advanced knowledge of upcoming natural disasters that are heading towards them, or what damage they could cause in a best and worst case scenario.

How Might We:
How might we help people determine how dangerous a natural disaster (hurricane, tornado, earthquake, typhoon, etc.) could be in the most advanced way possible by giving the user the best and worst case scenarios possible?
